4-1 RECEIVER CIRCUITS

4-1-1 ANTENNA SWITCHING CIRCUIT

The antenna switching circuit functions as a low-pass filter while receiving and a resonator circuit while transmitting. The circuit does not allow transmit signals to enter receiver circuits. Received signals enter the antenna connector (J1) and pass through the low-pass filter. The filtered signals are passed through the $\lambda/4$ type antenna switching circuit (D4–D6) and applied to the RF circuit.

4-1-2 RF AND 1ST MIXER CIRCUITS

• IC-F1500

The 1st mixer circuit converts the received signals to a fixed frequency of the 1st IF signal with the PLL output frequency. By changing the PLL frequency, only the desired frequency will be passed through a pair of crystal filters at the next stage of the 1st mixer.

The signals from the antenna switching circuit are passed through the tunable bandpass filter (D8) and amplified at the RF amplifier (Q1). The amplified signals are again passed through the tunable bandpass filter (D9–D11) and applied to the 1st mixer.

The filtered signals are mixed at the 1st mixer (Q2) with a 1st LO signal coming from the RX VCO circuit to produce the 1st IF signal (21.8 MHz). The 1st IF signal is passed through the matching circuit (L15, L52) and a pair of crystal filters (F11) to suppress out-of-band signals. The filtered signal is amplified at the 1st IF amplifier (Q4) and then applied to the 2nd IF circuit.

• IC-F2500

The signals from the antenna switching circuit are applied to the RF amplifier (Q1) via the tunable bandpass filter (D7, D8). The amplified signals are applied to the 1st mixer circuit (Q2) after passing through the tunable bandpass filter (D9–D11).

The applied signals are converted into the 30.875 MHz 1st IF signal at the 1st mixer circuit (Q2), and the 1st IF signal is filtered at the bandpass filter (F11) via the matching circuit (L15, L66).

The filtered signal is then applied to the 2nd IF circuit after being amplified at the IF amplifier (Q4).

4-1-3 2ND IF AND DEMODULATOR CIRCUITS

The 2nd mixer circuit converts the 1st IF signal to the 2nd IF signal. A double-conversion superheterodyne system improves the image rejection ratio and obtains stable receiver gain.

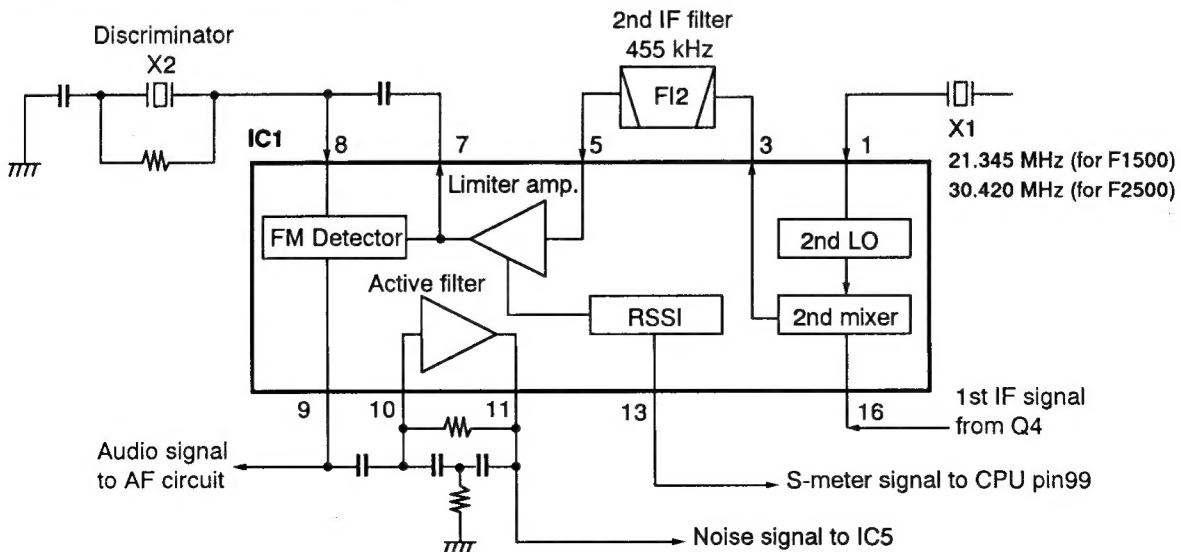

The 1st IF signal from the IF amplifier (Q4) is applied to the 2nd mixer section of the FM IF IC (IC1, pin 16) and is then mixed with the 2nd LO signal for conversion to 455 kHz 2nd IF signal.

The FM IF IC (IC1) contains the 2nd mixer, 2nd local oscillator, limiter amplifier, quadrature detector, active filter and audio amplifier. The local oscillator section generates 21.345 MHz (for F1500) / 30.420 MHz (for F2500) using X1.

The 2nd IF signal from the 2nd mixer (IC1, pin 3) passes through the ceramic filter (F12) to suppress unwanted heterodyned frequency signals. It is then amplified at the limiter amplifier section (IC1, pin 5) and applied to the quadrature detector section (IC1, pins 7, 8 and X2) to demodulate the 2nd IF signal into AF signals.

The AF signals are output from pin 9 and are then applied to the AF circuit.

• 2ND IF AND DEMODULATOR CIRCUITS

4-1-4 AF CIRCUIT

AF signals from IC1 (pin 9) are amplified at the AF amplifier (IC2) and are then applied to the high-pass filter (IC3). The characteristics of the high-pass filters are controlled by the "HFSW" signal. When "HFSW" is "High" the cut off frequency is shifted higher to remove CTCSS signals.

The filtered signals from IC3 (pin 1) are passed through the de-emphasis circuit (R68, C74) with frequency characteristics of - 6 dB/octave, and are then applied to the electronic volume controller (IC7, pin 2) via the AF mute switch (Q6).

Output signals from IC7 (pin 9) are applied to the AF power amplifier (IC8) to drive the speaker.

4-1-5 RECEIVE MUTE CIRCUITS

• NOISE SQUELCH

A squelch circuit cuts out AF signals when no RF signal is received. By detecting noise components in the AF signals, the squelch circuit switches the AF mute switch.

A portion of the AF signals from the FM IF IC (IC1, pin 9) are applied to the active filter section in IC1 (pin 10). Noise components are amplified and output from pin 11 (IC1).

The noise signals from IC1 (pin 11) are passed through a level controller (IC5, pins 21, 22) and are then converted to pulse type signals (NOIS) at the limiter amplifier (Q9, Q10).

The "NOIS" signals from the limiter amplifier (Q9, Q10) are applied to the CPU (IC20, pin 19). The CPU analyzes the signal strength by the number of pulses, and controls the AF switches (Q6, Q7) to cut out AF signals via the "AMUT" and "SP" lines.

• CTCSS

A portion of the AF signals from the AF amplifier (IC2) pass through the low-pass filters (IC4a/b) and are then amplified at the tone amplifier (IC28a). The amplified signals are applied to the CPU (IC20, pin 98) to decode the applied CTCSS signal.

• MICROPHONE AMPLIFIER CIRCUIT

4-2 TRANSMITTER CIRCUITS

4-2-1 MICROPHONE AMPLIFIER CIRCUIT

The microphone amplifier circuit amplifies the audio signals with +6 dB/octave pre-emphasis characteristics from the microphone to a level needed for the modulation circuit.

Audio signals from the connected microphone are applied to the MIC switch (IC25) via the FRONT unit and J5 (MAIN unit, pin 10). While transmitting, the MCON signal from the CPU is "High" and the AF signals pass to the microphone amplifier circuit.

The audio signals from the MIC switch (IC25, pin 6) are amplified at the preamplifier (IC21b), and then applied to the HPF amplifier section in IC22 (pin 16).

The amplified signals are pre-emphasized with +6 dB/octave at a limiter amplifier (pins 14, 12), then passed through a splatter filter (pins 7, 8). The output signals from pin 8 (IC22) pass through the level controller (IC5, pins 3, 4) and are then applied to the modulation circuit.

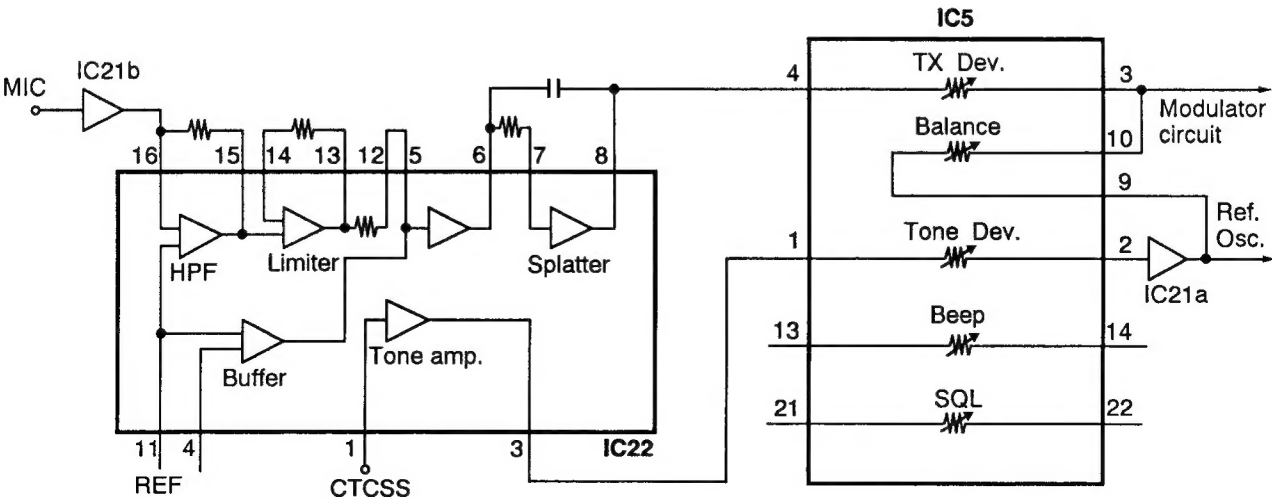

4-2-2 MODULATION CIRCUIT

• IC-F1500

The modulation circuit modulates the VCO oscillating signal (RF signal) using the microphone audio signals.

The audio signals from the level controller (IC5) are amplified at Q52 and then change the reactance of D23 and D46 to modulate the oscillated signal at the TX VCO circuit (Q23). The modulated signal is amplified at the buffer amplifiers (Q19, Q20) and is then applied to the drive amplifier circuit via the T/R switching circuit (D17).

CTCSS signals from the CPU (IC20, pins 32-35) are applied to the tone amplifier section in IC22 (pin 1). The amplified signals from the tone amplifier (IC22, pin 3) pass through the level controller (IC5, pins 1, 2) and are then applied to the VCO circuit via the low-pass filter circuit (IC21a).

• IC-F2500

The audio signals from the level controller (IC5) change the reactance of D23 to modulate the oscillated signal at the TX VCO circuit (Q23). The VCO output is amplified at the buffer amplifiers (Q19, Q20).

CTCSS signals from the CPU (IC20, pins 32–35) pass through the level controller (IC5, pins 1, 2) and are then applied to the VCO or REF circuit via the low-pass filter circuit (IC21a)

4-2-3 DRIVE / POWER AMPLIFIER CIRCUITS

• IC-F1500

The signal from the buffer amplifier (Q20) is passed through the T/R switching circuit (D17), and amplified by the drivers (Q15–Q17) and the power module (IC11) to obtain 25 W of RF power.

The amplified signal is passed through the antenna switching circuit (D4), low-pass filter and APC detector, and is then applied to the antenna connector.

The collector voltages for drivers (Q15, Q16) come from the MT8V regulator circuit (Q38). The transmit mute switch (Q39) controls the MT8V regulator when transmit mute is necessary.

• IC-F2500

The driver amplifier (Q15–Q17) and the power module (IC11) amplify the VCO oscillating signal from the T/R switching circuit to obtain 25 W of RF power. The amplified signal is passed through the antenna switching circuit (D4), low-pass filter and APC detector, and is then applied to the antenna connector.

The collector voltages for driver (Q16) come from the MT8V regulator circuit (Q38), and the collector voltages for driver (Q15) and the control voltage for power amplifier (IC11) come from the APC circuit (Q11).

4-2-4 APC CIRCUIT

The APC circuit protects the power module (IC11) and drive amplifier (Q15; IC-F2500 only) from a mismatched output load and stabilizes the output power.

The APC detector circuit detects forward signals and reflection signals at D3 and D1 respectively. The combined voltage is at a minimum level when the antenna impedance is matched at 50 Ω and is increased when it is mismatched.

The detected voltage is applied to the inverse amplifier (IC10b, pin 5), and the power setting voltage (PSET) is applied to the other input (IC10b, pin 6) via the amplifier (IC10a) for reference. When antenna impedance is mismatched, the detected voltage exceeds the power setting voltage. Then the output voltage of the inverse amplifier (IC10b, pin 7) controls the input current of the drive amplifier (Q15; F2500 only) and the power module (IC11) to decrease the output power.

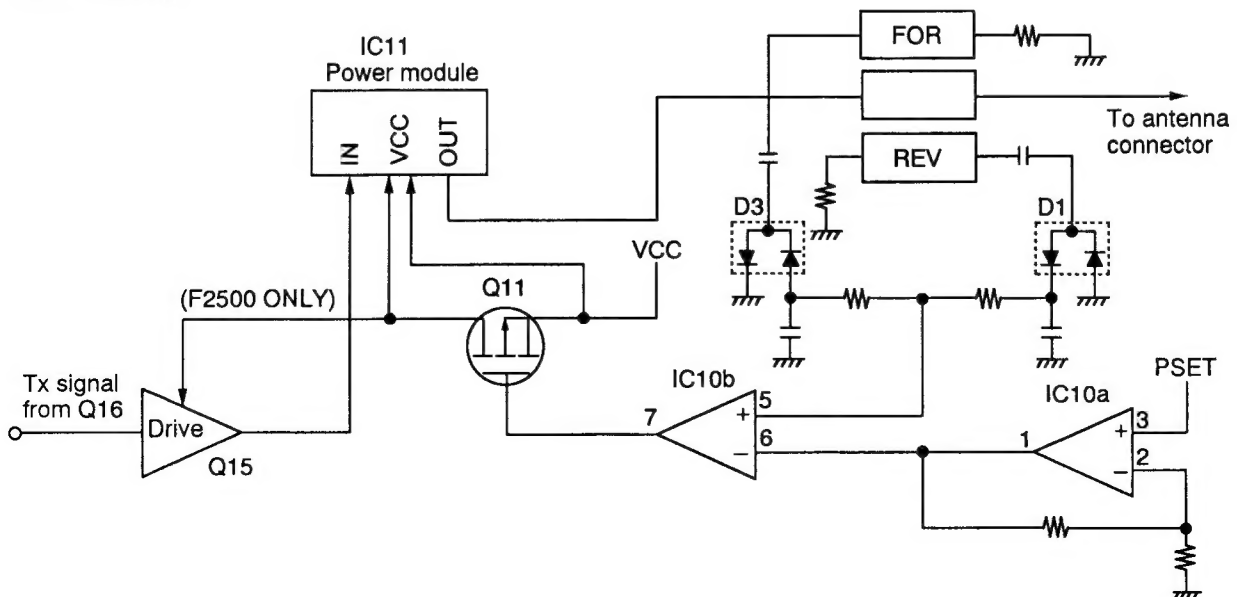

4-3 PLL CIRCUITS

4-3-1 PLL CIRCUIT

A PLL circuit provides stable oscillation of the transmit frequency and the receive 1st LO frequency. The PLL circuit consists of the PLL IC (IC12), charge pump, loop filter and reference oscillator and employs a pulse swallow counter.

Signals from the VCO through buffer amplifiers (Q18, Q19) are prescaled in the PLL IC (IC12) based on the divided ratio (N-data). The PLL IC detects the out-of-step phase using the reference and outputs it from pin 6 (IC12). The output signal is passed through the charge pump (Q30–Q33) and loop filters (R153/C179, R154/C181), and is then applied to the VCO circuit as the lock voltage.

• APC CIRCUIT

The accelerator switch (IC13a/b) selects the effective loop filter to accelerate the lock up speed.

The lock voltage is also used for the receiver tunable bandpass filters to match the filter's center frequency to the desired receive frequency. The lock voltage is amplified at the buffer amplifier (Q29) and is then applied to the band-pass filters (D8–D11: F1500, D7–D11: F2500).

4-3-2 VCO CIRCUIT

• IC-F1500

The VCO circuit contains a separate RX VCO (Q21, D19, D20, D40, D41) and TX VCO (Q23, D21, D22, D42, D43). The oscillated signal is amplified at the buffer amplifiers (Q19, Q20) and is then applied to the T/R switching circuit (D17, D18). The signal from the RX VCO circuit is applied to the 1st mixer (Q2) via the LO amplifier (Q3) and the TX VCO signal to the driver (Q17).

A portion of the signal from Q19 is amplified at the buffer amplifier (Q18) and is then fed back to the PLL IC (IC12, pin 11) as the comparison signal.

• IC-F2500

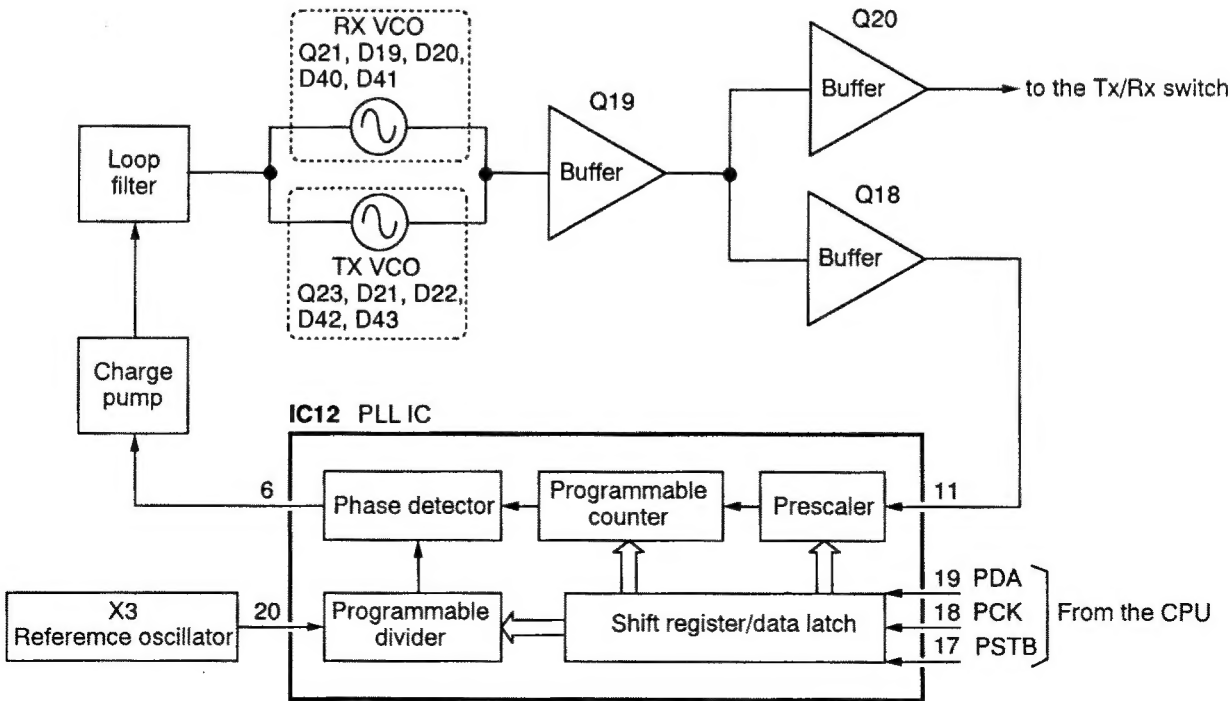

The RX VCO consists of Q21, D19 and D20, and the TX VCO consists of Q23, D21 and D22. The oscillated signal is applied to the T/R switching circuit (D17, D18) after being amplified at the buffer amplifier (Q19, Q20).
